Clearly beautiful

CLEAR Ceramic™ Bracket

A solid single crystal, continuous edge to edge with no grain boundaries produces maximum optical clarity

Most of the ceramic brackets on the market are made out of either polycrystalline or monocrystalline sapphire. The primary difference between these two materials is their optical clarity. Monocrystalline alumina ceramic brackets have a more translucent (clearer) appearance whereas polycrystalline brackets are more whitish (tooth colored). This form of alumina has been selected because of its superior physical strength and favorable optical and aesthetic properties. Our ceramics are nonporous, resistant to staining and eliminate the absorption of odors.

The Science behind bond strength

Micrographs show clearly our unique Double Fusion Method. The base of the bracket is coated with Zirconia powder, which produces Spheroid particles; each particle has a mass of tiny dendrites. These properties allow for a secure retention during the length of treatment and provide predictable and safe debonding at the end of treatment.

Correct material produces big advantages

Monocrystalline Sapphire alumina has a modulus of rupture greater than 35,000 psi (241.3 MPa). This strength is essential to producing a ceramic bracket without breakage issues. Standard ceramic brackets are rather bulky as they have to overcome the physical property limitations of other types of material, so they tend to be somewhat uncomfortable to the patient.

Monocrystalline Sapphire's strength enables us to offer a small and comfortable bracket for the patient. It offers our orthodontists the mechanical strength needed for predictable treatment.

DISCREET™ Ultra-Low Friction Bracket

Uniting brilliant aesthetics with outstanding ultra-low frictional forces

Research reports 30% less friction than common ceramics

During fixed appliance therapy, friction generated at the bracket/wire and wire/ligature interfaces is a critical factor in determining the efficiency of biological tooth movement. The increase in frictional forces within the aesthetic line has been well documented over the years. The challenge was how to produce an aesthetic bracket that could satisfy the demand for optimal appearance and performance.

Surface roughness plays a large role in the production of frictional forces in the majority of aesthetic brackets. Material selection and manufacturing methods needed to be revised to produce a smoother surface. A new combination of compounds which includes ceramic took advantage of properties found in these new atomic structures, and produced the ultra smooth surface we needed to decrease friction but continue to maintain high optical clarity.

We also used a new manufacturing method called Laser Sintering, used in the past to produce products that require a mirror polished surface like kitchen utensils, ophthalmic lenses, watch faces, could now be used for the production of aesthetic brackets, producing the smoothest results possible.

Ultra-low friction

The new material composition of the bracket shows in comparison to all other common aesthetic bracket materials on the market superior low frictional forces and provides premium sliding mechanics

Safe debonding

Highest bonding strength combined with fracture-less debonding of the bracket ensures optimal protection of the dental enamel

Precise tolerances

This one-piece-bracket is manufactured with a unique laser aided sintering technology, allowing complex and precise bracket shapes with smallest slot tolerances for optimum performance of the prescription

Endless clarity & translucency

The DISCREET™ assures true clarity during the entire treatment process. Even after a 24hr Curry bath no discoloring of the material was recorded

Fractural toughness

Manufacturing methods, material selection, and optimum morphology produces a bracket that can withstand the rigours of orthodontic forces

Significant reduction in attrition of teeth

Attrition of teeth is prevalent with all other common ceramic brackets. Combining new compounds has produced a strong reliable bracket but eliminates the extreme hardness of the common ceramic bracket

Biocompatibility

The combination of different translucent materials, including ceramic, ensures outstanding high biocompatibility. Our combination of compounds are CE-certified and approved by biocompatible tests like mutagen, skin sensitization, cytotoxicity and oral toxicity

Outstanding low frictional forces for optimal sliding mechanics produces reliable, predictable control of treatment.

Frictional Force in N - Offset test

Exceptional torque fracture resistance creates accurate rotation control and reduces breakages during treatment.

Average Torque Strength in Ncm

Safe, reliable and predictable debonding

Mechanical retention is achieved through indentations and added undercuts in the base of the bracket. Laboratory testing indicated that the mean linear tensile strength of enamel is 14.5MPa. The force required for debonding falls within a range safe for the enamel yet strong enough to hold throughout full orthodontic treatment.
